Configuration Split  
Module in Drupal 8/9

# Agenda

- Introduction
- Configuration Split module
- Setup & Configuring the module
- Creating split directories
- Creating split configuration
- Demo
- Alternate modules in use

# Introduction

- The Drupal **Configuration Management System** is one of the best additions to Drupal 8 (and continues to be present in Drupal 9).
- In Drupal, **configuration** is the collection of admin settings that determine how the site functions, as opposed to the content of the site.
- With the **Configuration Manager** core module, you can import, export, and synchronize site configuration via **Manage > Configuration > Development > Configuration synchronization** (admin/config/development/configuration)

# Configuration Split module

- Few key requirements that are missing in Drupal core configuration management system can be fulfilled by **Configuration Split** module.
- There are cases where certain configurations like modules/credentials need to be enabled only in certain environments.
- This module allows for conditional configuration by defining sets of configuration that will get exported to separate directories when exporting and gets merged together when importing.

# Setup & Configuring the module

- Installing the Configuration split module is like installing any other contributed module ([https://www.drupal.org/project/config\\_split](https://www.drupal.org/project/config_split)).
- Use Composer to install as it automatically installs all of the necessary dependencies ([Config Filter](#) module). Open the terminal within the project and enter the following command:

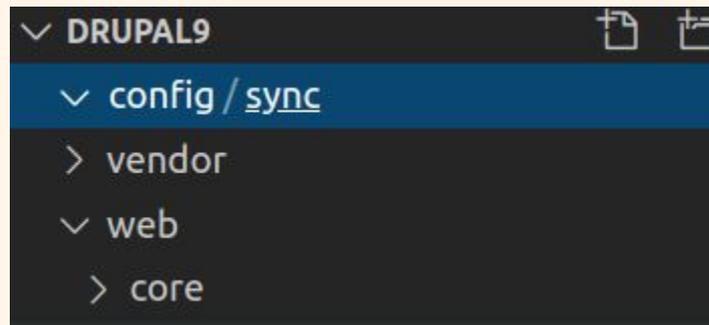

```
$ composer require drupal/config_split
```

# Creating split directories

- After installing and enabling the module, we can create one or more "splits" in which to divide up our configuration.
- Now let's take a look at the config management directories:

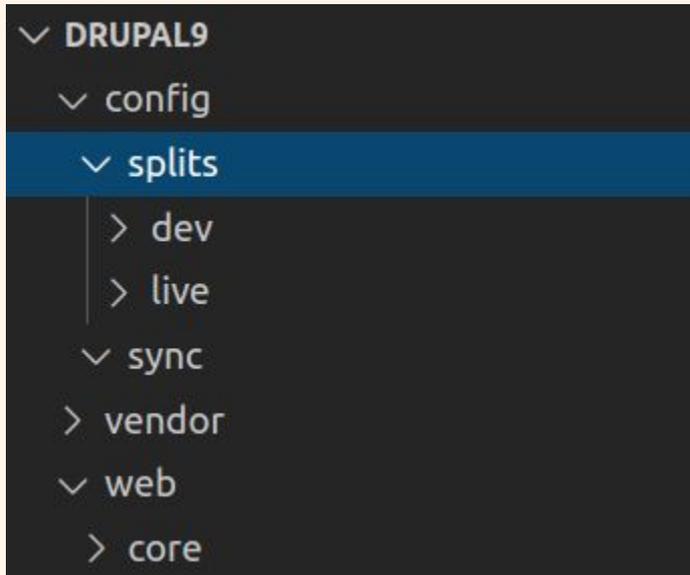

The `sync` directory is under the `config` directory, which is a sibling directory to our `web`:

# Creating split directories

To create a new directory for our development split, we create a `dev` directory and for live split, we create a `live` directory in our config directory:

# Creating split configuration

- Navigate to **Admin > Configuration > Development > Configuration Split Settings** and click on “Add Configuration Split Setting”.
- Enter a Label of your choice.
- Under Static Settings, enter the web-relative path to the split directory in the folder field and uncheck “Active” checkbox.
- Click “Save” to save the new split.

# Creating split configuration

[Home](#) [Administration](#) [Configuration](#) [Development](#) [Synchronize](#)

## Configuration Split setting

[+ Add Configuration Split setting](#)

Configuration Split setting	Machine name	Description	Status	Operations
<a href="#">Dev</a>	dev	Development environment-specific configuration.	inactive	<a href="#">Edit</a>
<a href="#">Live</a>	live	Live environment-specific configuration.	inactive	<a href="#">Edit</a>

# Creating split configuration

- Next up, let's modify our settings.php file to dynamically enable our splits based on the current environment.

```
$config['config_split.config_split.the_split_name'] [  
    'status'] = TRUE;
```

Where:

**the\_split\_name** is machine name of the split we created earlier.

# Creating split configuration

- Now if we look at the Config Split module's interface in our various environments, we should see that the appropriate split is enabled for each one.
  - “Dev” split is enabled in the `dev` environment.

Home > Administration > Configuration > Development > Synchronize

## Configuration Split setting ☆

+ Add Configuration Split setting

Configuration Split setting	Machine name	Description	Status	Operations
<a href="#">Dev</a>	dev	Development environment-specific configuration.	active (overwritten)	Edit ▾
<a href="#">Live</a>	live	Live environment-specific configuration.	inactive	Edit ▾

# Creating split configuration

- “Live” split is enabled in the **live** environment.

Home > Administration > Configuration > Development > Synchronize

## Configuration Split setting ☆

+ Add Configuration Split setting

Configuration Split setting	Machine name	Description	Status	Operations
<a href="#">Dev</a>	dev	Development environment-specific configuration.	inactive	<a href="#">Edit</a> ▼
<a href="#">Live</a>	live	Live environment-specific configuration.	active (overwritten)	<a href="#">Edit</a> ▼

# Demo

# Alternate module - Configuration Ignore module

- This module helps to keep the configuration we want, in place and prevent it from overriding.
- Install and enable module - [https://www.drupal.org/project/config\\_ignore](https://www.drupal.org/project/config_ignore)
- Go to **Manage > Configuration > Development > Configuration synchronization > Ignore** (admin/config/development/configuration/ignore), add the name of the configuration that we want to ignore upon import and click on "Save configuration".

**Any Suggestions/Questions?**

**Thank You!**
